

T-test for difference of Mean

Suppose we want to test if two independent samples x_i ($i=1, 2, \dots, n_1$) and y_j ($j=1, 2, \dots, n_2$) of size n_1 and n_2 have been drawn from two normal populations with means μ_x and μ_y respectively.

Under the null hypothesis (H_0) that the samples have been drawn from the normal populations with means μ_x and μ_y under the assumption that the population variance are equal, i.e.

$$\sigma_x^2 = \sigma_y^2 = \sigma^2 \text{ (say)}$$

the statistic

$$t = \frac{(\bar{x} - \bar{y}) - (\mu_x - \mu_y)}{S \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}}$$

$$\text{where } S^2 = \frac{1}{n_1 + n_2 - 2} \left[\sum_i (x_i - \bar{x})^2 + \sum_j (y_j - \bar{y})^2 \right]$$

is an unbiased estimate of the common population variance σ^2 , follows student's t -test with $(n_1 + n_2 - 2)$ d.f.

Example Below are given the gain in weight (in kgs) of pigs fed on two diets A and B.

Gain in weight

Diet A: 25 32 30 34 24 14 32 24 30 31 35 25

Diet B: 44 34 22 10 47 31 40 30 32 35 18 21 35

29 22

Test if two diets differ significantly as regards to their effect on increase in weight.

Null hypothesis $H_0: \mu_x = \mu_y$, i.e. there is no significant difference between the mean increase in weight due to two diets.
Alternate hypothesis $H_1: \mu_x \neq \mu_y$

Sol

Diet A

Diet B

x	$x - \bar{x}$	$(x - \bar{x})^2$	y	$y - \bar{y}$	$(y - \bar{y})^2$
25	-3	9	44	14	196
32	4	16	34	4	16
30	2	4	22	-8	64
34	6	36	10	-20	400
24	-4	16	47	17	289
14	-14	196	31	1	1
32	4	16	40	10	100
24	-4	16	30	0	0
30	2	4	32	2	4
31	3	9	35	5	25
35	7	49	18	-12	144
25	-3	9	21	-9	81
$\Sigma x = 336$	$\Sigma(x - \bar{x}) = 0$	$\Sigma(x - \bar{x})^2 = 380$	35	5	25
			29	-1	1
			22	-8	64
			$\Sigma y = 450$	$\Sigma(y - \bar{y}) = 0$	$\Sigma(y - \bar{y})^2 = 1410$

$$\bar{x} = \frac{336}{12} = 28, \quad \bar{y} = \frac{450}{15} = 30$$

$$S^2 = \frac{1}{n_1 + n_2 - 2} [\Sigma(x - \bar{x})^2 + \Sigma(y - \bar{y})^2]$$

$$= \frac{1}{12 + 15 - 2} [380 + 1410] = 71.6$$

Under the null hypothesis

$$t = \frac{\bar{x} - \bar{y}}{\sqrt{S^2 \left(\frac{1}{n_1} + \frac{1}{n_2} \right)}} = \frac{28 - 30}{\sqrt{71.6 \left(\frac{1}{12} + \frac{1}{15} \right)}}$$

$$= \frac{-2}{\sqrt{10.74}} = -0.609$$

Tabulated $t_{0.05}$ for $(12+15-2)=25$

deg of freedom = 2.06

classmate

Date _____
Page _____

Conclusion: $|t| = 0.609 < \text{tabulated } t$
 H_0 may be accepted at 5% level of significance and we conclude that the two diets do not differ significantly as regards to their increase in weight.

Observation: What have you noted?

In single mean t -test, one sample was given and based on that sample, we were testing whether the sample can be considered to have come from a normal population with a hypothetical mean.

But in t -test for difference of mean, we have two samples of different sizes and we are testing whether they have been drawn from two different normal populations.

Ex ② Samples of two types of electric bulbs were tested for length of life and following data were obtained.

	Type I	Type II
Sample No	$n_1 = 8$	$n_2 = 7$
Sample means	$\bar{x}_1 = 1234 \text{ hrs}$	$\bar{x}_2 = 1036 \text{ hrs}$
Sample S.D.'s	$S_1 = 36 \text{ hrs}$	$S_2 = 40 \text{ hrs}$

Is the difference in means sufficient to warrant that type I is superior to type II regarding the length of life?

[Note - Here again we have two samples and we want to test whether they come from same normal population or type I is superior (This is right tailed)]

Null hypothesis $H_0: \mu_x = \mu_y$, the two types I and II of electric bulbs are identical.
 Alternative hypothesis: $H_1: \mu_x > \mu_y$, i.e. type I is superior to type II

Test statistics

$$t = \frac{\bar{x}_1 - \bar{x}_2}{\sqrt{S^2 \left(\frac{1}{n_1} + \frac{1}{n_2} \right)}}$$

where

$$\begin{aligned} S^2 &= \frac{1}{n_1 + n_2 - 2} \left[\sum (x_i - \bar{x}_1)^2 + \sum (y_i - \bar{y}_1)^2 \right] \\ &= \frac{1}{n_1 + n_2 - 2} \left[n_1 s_1^2 + n_2 s_2^2 \right] \\ &= \frac{1}{13} \left[8 \times 36^2 + 7 \times 40^2 \right] \\ &= 1659.08 \end{aligned}$$

$$\begin{aligned} t &= \frac{1234 - 1036}{\sqrt{1659.08 \left(\frac{1}{8} + \frac{1}{7} \right)}} = \frac{198}{\sqrt{1659.08 \times 0.2679}} \\ &= 9.39 \end{aligned}$$

Tabulated t for 13 deg of freedom at 5% level for right (single) tailed test is 1.77

$$9.39 > 1.77$$

Conclusion: Null hypothesis is rejected as calculated t is much greater than tabulated t value.

Hence type I is definitely superior.
